# ISDCF Closed Caption Authoring Best Practices 

Revised 21 January 2015

Revised 11 February 2016

## Introduction

This document summarizes information in JPEG Interop Group Closed Caption Packaging, SMPTE 428-10, and closed captioning systems currently being manufactured. It is intended to help closed caption authors in creating captions that will work on the largest number of systems.

Closed captions use the timed text file format defined in SMPTE 428-7. The file is constrained by the above cited documents to work on personal display devices. Each of the constraints are discussed below. Since the same type of devices are used for closed subtitles as for closed captions, these constraints also apply to closed subtitles.

## Timed Text File Size

Some closed captioning systems may be limited in the size of the timed text file they can handle. Most of the existing system supports timed text XML file size of at least 256 kB . Some system may support higher size (e.g., up to 2 MB ). A timed text reel typically runs 100 kB , so this should not be an issue. It is possible to use a single timed text file for the entire composition and break it into reels using EntryPoint and Duration, however, this may not work in all current implementations if the file size is larger than 256kB.

## TimeIn, TimeOut, FadeUp, FadeDown, EntryPoint, Duration

Subtitles on the main screen may have overlapping display times resulting in more than one subtitle being present at the same time. Closed caption devices can only display one caption at a time. SMPTE 428-7 states that the subtitle shall complete its fade out at TimeOut. Further, closed caption display devices do not support FadeUp and FadeDown. A caption will be fully visible at Timeln and fully invisible at TimeOut. The TimeIn of a caption must be equal to or later than the TimeOut of the previous caption, if any. When a caption straddles a reel boundary, it should be presented twice, once in the old reel, and once in the new reel. The old reel should have a TimeOut equal to the last edit unit of the reel. The Timeln on the new reel should be the first edit unit of the new reel.

EntryPoint and Duration allow the composition playlist (CPL) to perform the equivalent of a film "butt splice." Captions in a reel that are before the entry point or after entry point + duration will not be shown. Captions that start before the entry point but end after the entry point will be shown for a shorter period of time (from EntryPoint to TimeOut). Similarly, captions that start before EntryPoint + Duration but end after EntryPoint + Duration will be shortened.

Caption authors are encouraged to use appropriate timing to ensure users have enough time to read the caption. A minimum time for a short caption of 0.5 seconds is suggested.

## Image

While on-screen subtitles can be PNG images, closed captions cannot. Closed captions must use Text elements to contain the caption text.

## Ruby Text

Ruby text is not supported by closed caption devices.

## Halign and Hposition

Halign may be used within a Subtitle or Text element to left, center, or right justify the closed caption text. Some closed caption displays use Halign to horizontally position the text, while others ignore Halign and always align to the left or center. Authors should not count on Halign positioning text as desired on all devices. The Hposition attribute is ignored by closed caption devices.

## Valign and Vposition

Some, but not all, systems interpret Valign and Vposition as specified in SMPTE 428-10. To ensure captions display correctly on all devices:

- The Text elements of each caption should be in the order they are to be displayed.
- The text that is to display on the first line should be in the first Text element in the Subtitle element.
- Valign and Vposition should be in accordance with SMPTE 428-10. If Valign is "top" or "center," the Vposition of each Text element within a subtitle element should be higher than the previous. If Valign is "bottom," the Vposition of each Text element within a Subtitle element should be lower than the previous.

Valign may be used in a Text element. If Valign is not used, it takes on its default value of "center." Valign for each Text element within a single Subtitle element must be the same.

## Direction Attribute

Closed caption devices ignore the Direction attribute of the Text element and always display text left to right. Further, closed caption devices do not implement the Unicode bidirectional algorithm and ignore related elements and marks (bdi, LRM, RLM, etc.).

## LoadFont, Font, and Font Attributes

Closed caption displays use an internal device-specific font. These devices ignore the LoadFont and Font elements. Current devices also ignore font attributes such as Italic. The inclusion of a font file and a LoadFont element in a closed caption timed text file is not expected to cause a problem. There IS a problem if there is a LoadFont element that refers to a font file that is not present.

## Text

The closed caption text is enclosed in a Text element. Each line of the closed caption is in an individual Text element. Closed caption devices are currently limited to three lines of text, so an individual closed caption may have a maximum of three Text elements.

Closed caption devices support a limited number of characters per line. For the character set that is common to all devices (in the next section), most current devices will generally support 30 characters per line. Most systems used fixed width characters with 32 characters per line, but some use variable width characters where the number of characters per line varies depending on which characters are used. If more characters with larger width are included in a line, fewer characters may be rendered in the line causing unintended line break or loss of text. Authors of closed captions should be aware of the nature of the variable width font. With typical text, 30 characters (whether fixed or variable width) per line can be assumed.

Most systems support word wrap if a line of text is longer than can be displayed on a line. In most systems, the remainder of a line is shown on the next line by itself. For example, if the first line was too long to fit, the words that would not fit would be shown on the second line. The second line of text would then be displayed on the third line. If there were a third line of text, it would not be displayed. However, some systems remove line breaks if there is word wrap. In the example, the first line of text would be continued on the second line. Then the second line of text would be shown on the second line, perhaps overflowing to the third line. As much of the third line of text as possible would be displayed on the third line.

Caption lines should be limited to 30 characters to avoid word wrap.

## Supported Characters

Characters are encoded in Text elements using UTF-8. Since some characters are reserved in XML, "character entities" are used for a small number of characters. XML also supports numbered character references of the form \&\#xxxx; and \&\#xyyyy; where xxxx is the Unicode code point in decimal, and yyyy is the Unicode code point in hexadecimal. Support for numbered character references and named character entities varies.

The character set supported by most existing closed captioning systems is listed below. This is ISO 88591 plus the character U+266A ( ס). Some closed captioning systems may support additional characters, including double width Asian characters. The preferred encoding that is supported by the largest number of suppliers is marked in green.

| Character | Unicode | UTF-8 | XML <br> Predefined <br> Entity | Character <br> Reference <br> Decimal | Character <br> Reference Hex |
